Hepatocellular carcinoma (HCC) is the third cause of cancer-related death worldwide. When these tumors are in advanced stages, few therapeutic options are available. Therefore, it is essential to search for new treatments to fight this disease. In this study, we investigated the effects of cannabinoids – a novel family of potential anticancer agents – on the growth of HCC. We found that Δ\textsuperscript{9}-tetrahydrocannabinol (Δ\textsuperscript{9}-THC, the main active component of Cannabis sativa) and JWH-015 (a cannabinoid receptor 2 (CB\textsubscript{2}) cannabinoid receptor-selective agonist) reduced the viability of the human HCC cell lines HepG2 (human hepatocellular liver carcinoma cell line) and HuH-7 (hepatocellular carcinoma cells), an effect that relied on the stimulation of CB\textsubscript{2} receptor. We also found that Δ\textsuperscript{9}-THC- and JWH-015-induced autophagy relies on tribbles homolog 3 (TRB3) upregulation, and subsequent inhibition of the serine–threonine kinase Akt/mammalian target of rapamycin C1 axis and adenosine monophosphate-activated kinase (AMPK) stimulation. Pharmacological and genetic inhibition of AMPK upstream kinases supported that calmodulin-activated kinase kinase \(\beta\) was responsible for cannabinoid-induced AMPK activation and autophagy. 

In vivo studies revealed that Δ\textsuperscript{9}-THC and JWH-015 reduced the growth of HCC subcutaneous xenografts, an effect that was not evident when autophagy was genetically or pharmacologically inhibited in those tumors. Moreover, cannabinoids were also able to inhibit tumor growth and ascites in an orthotopic model of HCC xenograft. Our findings may contribute to the design of new therapeutic strategies for the management of HCC.

Cell Death and Differentiation (2011) 18, 1099–1111; doi:10.1038/cdd.2011.32; published online 8 April 2011

Hepatocellular carcinoma (HCC) is one of the most common solid tumors and the third leading cause of cancer-related death worldwide.\textsuperscript{1} Its prognosis remains reserved, with a 5-year survival rate of <5%.\textsuperscript{2} It is the most common cause of death in patients with cirrhosis\textsuperscript{3} and, according to the World Health Organization, the incidence of HCC is expected to increase until 2030. The overall survival of patients with HCC has not significantly improved in the past two decades. Current treatments are only applicable at early stages of tumor development and include tumor resection, liver transplantation, chemoembolization and sorafenib administration.\textsuperscript{4} However, approximately half of the patients suffer tumor recurrence. The most important mechanism of liver cancer progression is cell proliferation. Although in recent years several clinical trials have tested the efficacy of agents that selectively target important signaling pathways involved in the control of this process, no relevant improvement in the prognostic/survival of patients with HCC has been achieved so far,\textsuperscript{5} and, therefore, it is necessary to identify novel therapeutic strategies for the management of HCC.

Cannabinoids are lipid mediators originally isolated from the hemp plant Cannabis sativa that produce their effects by activating primarily two G-protein-coupled receptors: cannabinoid receptor 1 (CB\textsubscript{1}), which is highly abundant in the brain, and cannabinoid receptor 2 (CB\textsubscript{2}), which is mainly expressed in non-neural tissues. Recently, numerous studies have evidenced the role of cannabinoids as potential anti-tumoral drugs owing to their ability to reduce tumor in different animal models, including glioma,\textsuperscript{6} breast cancer\textsuperscript{7,8} and prostate cancer.\textsuperscript{9,10} Recent research has also reported that the synthetic cannabinoid WIN-55 212-2 inhibits HCC growth.\textsuperscript{11,12}

It has been described that Δ\textsuperscript{9}-tetrahydrocannabinol (Δ\textsuperscript{9}-THC, the main active constituent of marijuana, triggers human glioma cell death through stimulation of an ER stress pathway that activates autophagy and promotes apoptosis.\textsuperscript{13,14} Autophagy is a cellular self-digestive process

whereby bulk cytoplasmic components and intracellular organelles are sequestered into double-membrane vesicles named autophagosomes and delivered for degradation to the lysosomes. In the liver, autophagy may have an important role in the regulation of energy balance for basic cell functions. Although functional autophagy acts as a metabolic stress buffer, many lines of evidence support a role for autophagy in antagonizing cell survival and in promoting cell death and apoptosis. Autophagy has an important role in cancer, and inhibition of this cellular process has been proposed to contribute to HCC progression, and, therefore, it is a potentially very important target for liver cancer prevention and treatment.

This study was therefore undertaken to evaluate the potential anti-tumoral activity of cannabinoids in HCC and the mechanisms responsible for cannabinoid action in that devastating disease. We found that, both in cell cultures and in xenografted mice, Δ9-THC and the synthetic CB2 receptor-selective agonist JWH-015 promote human HCC death via autophagy stimulation. We also provide a molecular mechanism underlying CB2 receptor-mediated anti-tumoral signaling. These observations may pave the way to the design of novel therapeutic strategies for the treatment of hepatocellular carcinoma.

Results

Δ9-THC- and JWH-015-induced autophagy and apoptosis relies on CB2 receptor activation. To investigate the activity of cannabinoids on HCC cells, we first analyzed the effect of Δ9-THC (a CB1/CB2 receptor-mixed agonist that constitutes the main psychoactive ingredient of Cannabis sativa) and JWH-015 (a CB2 receptor-selective agonist) on HepG2 (human hepatocellular liver carcinoma cell line) and HuH-7 (hepatocellular carcinoma cells) cells, two HCC lines that express CB1 and CB2 cannabinoid receptors (Supplementary Figure 1A). Treatment with Δ9-THC reduced the viability of HepG2 and HuH-7 cells, an event that was prevented by co-incubation with SR144528 (SR2, a CB2 receptor-selective antagonist), but not with SR141716A (SR1, a CB1 receptor-selective antagonist) (Supplementary Figure 1B). Likewise, JWH-015 decreased the viability of HCC cells, and co-incubation with SR2 abrogated this effect (Supplementary Figure 1B). These observations support that stimulation of CB2 receptors is responsible for the decrease of cell viability triggered by cannabinoids on HCC cells.

Δ9-THC and JWH-015 inhibit the growth of the human HCC lines HepG2 and HuH-7 via autophagy stimulation. It has been recently shown that cannabinoids induce human glioma cell death via autophagy stimulation in vitro and in vivo. We therefore examined whether Δ9-THC and JWH-015 activate a similar mechanism in HCC cells. Upon autophagy stimulation, the autophagy protein LC3 (microtubule-associated protein 1 light chain 3α) becomes conjugated to phosphatidylethanolamine (PE), which targets this protein to the membrane of the autophagosomes. The lipidated autophagosome-associated form of LC3 (LC3-II) can be monitored by immunofluorescence (autophagic cells exhibit a characteristic pattern of LC3 puncta) or western blot (LC3-II has higher electrophoretic mobility than non-lipidated LC3). Immunofluorescence analysis revealed that LC3 exhibited a punctuated distribution, consistent with its translocation to the autophagosome, in cells that had been treated with Δ9-THC or JWH-015 (Figure 1a). Likewise, incubation of HepG2 and HuH-7 cells with Δ9-THC or JWH-015 increased the levels of the lipidated form of LC3 (Figure 1b). Furthermore, pharmacological inhibition with E64d and pepstatin A (PA) of lysosomal proteases (the enzymes responsible for the degradation of the autophagosome content after fusion with the lysosome) enhanced the accumulation of LC3-II (as well as of the autophagosome cargo p62) in cells that had been treated with THC or JWH-015, thus supporting the fact that cannabinoid treatment leads to dynamic autophagy in HCC cells (Figure 1b).

Next, we investigated whether autophagy was directly involved in the mechanism of cannabinoid-induced cell death. As shown in Figure 1c, cell death was inhibited when autophagy was pharmacologically blocked at a very early stage (by incubation with 3-methyladenine (3-MA), an inhibitor of Vps34, a class III phosphatidylinositol-3-kinase that has a crucial role in autophagy initiation) or at a final stage (by incubation with E64d and PA). Likewise, knock down of Atg5 (an essential autophagy gene that is part of one of the two protein conjugation systems required for autophagosome elongation) impaired THC- or JWH-015-induced cell death (Figure 1d). Taken together, these observations strongly support that autophagy is required for cannabinoid-induced HCC cell death.

Many lines of evidence indicate that there is a cross-talk between autophagy and apoptosis. To investigate whether cannabinoid-induced autophagy was involved in apoptosis induction, HepG2 and HuH-7 cells were incubated with either Δ9-THC or JWH-015 in the presence of the 3-MA, and levels of procaspase-3 were detected by immunoblot. As shown in Figure 1e, pre-incubation with 3-MA prevented the cleavage of procaspase-3, suggesting that autophagy induction by cannabinoids was previous to and necessary for apoptosis.

AMPK activation and TRB3 upregulation are involved in Δ9-THC- and JWH-015-induced autophagy and apoptosis of HCC cells. The mechanisms of autophagy stimulation by cannabinoids in glioma and other types of cancer cells relies on the stimulation of an ER stress-related pathway, which leads to the upregulation of the pseudokinase tribbles homolog 3 (TRB3). This latter protein interacts with serine–threonine kinase Akt (Akt) and promotes the inhibition of the mammalian target of rapamycin C1 (mTORC1) complex, which leads to autophagy stimulation. As shown in Figure 2, THC and JWH-015 increased the phosphorylation of the α-subunit of the eukaryotic translation initiation factor 2 (eIF2α), a hallmark of the ER stress response; Figure 2a), increased TRB3 levels (Figure 2b) and decreased the phosphorylation of Akt, p70S6 kinase (a well-established substrate of mTORC1) and the ribosomal protein S6 (a target of p70S6 kinase) in HepG2 and HuH-7 cells (Figure 2c). Furthermore, selective knockdown of TRB3 abrogated cannabinoid-induced inhibition of the Akt/mTOR pathway, autophagy and cell death (Supplementary Figure 2), thus supporting the fact that...
the mechanism by which cannabinoids promotes glioma cell death also operates in HCC cells.

Of note, we observed that treatment of HepG2 and HuH-7 cells with THC or JWH-015 increased the phosphorylation of adenosine monophosphate-activated protein kinase (AMPK), an important intracellular nutrient status sensor that has been proposed to have a critical role in the regulation of autophagy as induced by hypoxia or nutrient deprivation.

Figure 1  Δ⁹-Tetrahydrocannabinol (Δ⁹-THC) and JWH-015 treatment induces autophagy in hepatocellular carcinoma (HCC) cells. (a) HepG2 and HuH-7 cells were treated with Δ⁹-THC or JWH-015 for 24 h and microtubule-associated protein 1 light chain 3b (LC3) was detected by confocal immunofluorescence. Nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI). Values on the lower right corner of each panel correspond to the number of cells with LC3 dots relative to the total number of cells (n = 5; mean ± standard deviation (S.D.)). (b) Immunoblot analysis of p62, LC3-I and LC3-II levels after Δ⁹-THC or JWH-015 treatment in the presence of the lysosomal protease inhibitors E64d (2.5 μg/ml) and pepstatin A (5 μg/ml; PA) for 24 h. Tubulin levels are shown as loading control. (c) HepG2 and HuH-7 cells were treated either with 8 μM Δ⁹-THC or 8 μM JWH-015 in the presence of 2.5 μg/ml E64d and 5 μg/ml PA or 1 μM 3-methyladenine (3MA) for 48 h and cell viability was analyzed by 3-[4,5-dimethylthiazolyl-2]-2,5-diphenyl-tetrazolium bromide (MTT) test. Data are the mean ± S.D. of three different experiments each performed in triplicate (**P < 0.01 versus control; #P < 0.05 and ##P < 0.01 versus cannabinoid-treated cells). (d) Effect of Δ⁹-THC or JWH-015 on the viability – as determined by the MTT test (48 h) of HepG2 cells transfected with Atg5-selective (small interfering (si)Atg5) or control (siC) siRNA. Data correspond to the mean ± S.D. of three different experiments each performed in triplicate (**P < 0.01 versus control; ##P < 0.01 versus cannabinoid-treated cells). Atg5 mRNA levels (mean of the three experiments) assessed by real-time polymerase chain reactions (PCRs) are shown in the lower panel. (e) HepG2 or HuH-7 cells were incubated either with Δ⁹-THC or JWH-015 for 30 h in the presence of 1 μM 3-MA and levels of procaspase-3 and LC3 were detected by western blot. Tubulin levels are shown as loading control. The image is representative of three different experiments.
In addition, pharmacological blockade of CB2 receptors with SR2 abrogated the effect of Δ9-THC and JWH-015 on Akt, S6 and AMPK phosphorylation, as well as autophagy (Figure 2d and Supplementary Figure 1C). We therefore asked whether AMPK may also have a role in the regulation of the antiproliferative effect evoked by cannabinoids in HCC cells. In line with this notion, when AMPK was pharmacologically blocked with dorsomorphin (Figure 3a) or genetically inhibited with small interfering RNA (siRNA) (Figure 3b), HepG2 and HuH-7 cells were more resistant to cannabinoid-induced cell death. Likewise, AMPK knockdown prevented LC3 lipidation (Figure 3c and Supplementary Figure 2C). These observations support the fact that activation of AMPK is necessary for the
stimulation of autophagy-mediated cell death by cannabinoids in HCC cells.

AMPK and TRB3 regulate cannabinoid-induced autophagy of HCC cells through different mechanisms. AMPK has been shown to inhibit mTORC1.\textsuperscript{28} Unlike Akt, AMPK activates tuberous sclerosis complex 2 (TSC2), a GTPase-activating protein responsible for the blockade of mTORC1.\textsuperscript{28} Therefore, we next studied whether this was the mechanism by which AMPK stimulated autophagy in our system. As shown in Figure 3c and Supplementary Figure 2C, AMPK silencing abrogated the effect of Δ\textsuperscript{9}-THC and JWH-015 in the
phosphorylation of AMPK and its downstream target acetyl-CoA carboxylase (ACC), as well as on autophagy, but did not modify the effect of cannabinoid treatment on the phosphorylation of Akt, TSC2 (data not shown) or the mTORC1-related substrates 4EBP1 and S6. By contrast, TRB3 knockdown did not affect AMPK or ACC phosphorylation, but did inhibit the cannabinoid-induced decrease in Akt, TSC2, 4EBP1 and S6 phosphorylation and LC3 lipidation. Likewise, pharmacological blockade of ceramide biosynthesis by using ISP-1 (a pharmacological inhibitor of serine palmitoyltransferase, one of the upstream events that trigger TRB3 upregulation in response to cannabinoid treatment) abrogated the effect of Δ⁸-THC on Akt, TSC2, 4EBP1 and S6 phosphorylation, as well as LC3 lipidation, but did not affect AMPK phosphorylation. These observations support that the cannabinoid-evoked stimulation of autophagy on HCC cells relies on two different mechanisms: (i) inhibition of the Akt/mTORC1 axis via TRB3 upregulation and (ii) stimulation of AMPK. (A scheme is shown in Figure 5.)

**Activation of AMPK by cannabinoids relies on CAMKK.** We next investigated the mechanism by which cannabinoids activate AMPK. Among the different kinases proposed to act as AMPKKs, the human tumor suppressor liver kinase B1 (LKB1) and the calmodulin-activated kinase (CaMKK) are now widely accepted as the most relevant ones. Inhibition of LKB1 expression with siRNA did not have any significant effect on the viability of cannabinoid-treated HepG2 (Figure 4a) or HuH7 (Supplementary Figure 3) cells. Likewise, the effect of cannabinoid treatment on AMPK activation, Akt/mTORC1 pathway inhibition and autophagy (LC3 lipidation) was not affected by LKB1 silencing (Figure 4a), supporting the fact that LKB1 is not involved in cannabinoid-induced AMPK activation and autophagy in HCC cells. By contrast, selective knockdown of CaMKKβ or incubation with the CaMKK pharmacological inhibitor STO609 prevented the cannabinoid-evoked decrease in HCC cell viability (Figures 4b and c and Supplementary Figure 3), increase in AMPK and ACC phosphorylation (Figures 4b and c) and autophagy (Figures 4b and c), indicating that AMPK activation by cannabinoids in HCC cells relies on CaMKKβ. Of note, genetic or pharmacological blockade of CaMKKβ did not modify the inhibition of the Akt/mTORC1 pathway evoked by these agents, which again supports the fact that mTORC1 inhibition by cannabinoids in HCC occurs independently of AMPK activation (Figures 4b and c).

**Autophagy is required for Δ⁸-THC and JWH-015 anti-tumoral action in human HCC xenografts.** To investigate the ability of Δ⁸-THC and JWH-015 to inhibit HCC growth in vivo, we first generated tumor xenografts by subcutaneous inoculation of HepG2 or HuH-7 cells in nude mice. Mice were daily treated with vehicle (control), 15 mg/kg Δ⁸-THC or 1.5 mg/kg JWH-015 for 15 days. As shown in Figure 6a, cannabinoid administration almost totally blocked the growth of HepG2 cell-derived tumors. Moreover, treatment with Δ⁸-THC or JWH-015 enhanced AMPK phosphorylation and reduced Akt phosphorylation, which was accompanied by a decrease of S6 phosphorylation and an increase of LC3-II lipidation (Figure 6b). Likewise, prosapase-3 levels were also decreased in cannabinoid-treated tumors (Figure 5b). Similar results were obtained with HuH-7 cell-derived tumors, in which Δ⁸-THC or JWH-015 administration also decreased tumor growth (Figure 6c), increased the AMPK phosphorylation, decreased Akt and S6 phosphorylation and enhanced LC3 lipidation and caspase-3 activation (Figure 6d).

To further examine the role of autophagy on the anti-tumoral action of cannabinoids, another set of experiments was conducted to analyze the effect of cannabinoids on the growth of HepG2 tumor xenografts in which Atg5 expression had been knocked down. As shown in Figure 7a, Δ⁸-THC and JWH-015 failed to inhibit the growth of Atg5 silenced tumors, but not of those tumors that had been transfected with control siRNA. Furthermore, pharmacological inhibition of autophagy by using 3-MA prevented the decrease in tumor growth evoked by Δ⁸-THC and JWH-015 (Figure 7b). Taken together, these findings strongly support the fact that autophagy is necessary for the anti-tumoral action of cannabinoids in hepatocellular carcinoma.

Finally, we tested the anti-tumoral efficacy of cannabinoids in an orthotopic HCC model. HepG2 cells were inoculated in the liver of nude mice, and after 1 week, mice were treated intraperitoneally with vehicle (control), 15 mg/kg Δ⁸-THC or 1.5 mg/kg JWH-015 for 10 days. As shown in Figure 8a,

**Figure 4** Δ⁸-Tetrahydrocannabinol (Δ⁸-THC) and JWH-015 activate adenosine monophosphate-activated kinase AMPK via CaMKKβ. (a) Left panel: Effect of Δ⁸-THC (8 μM) or JWH-015 (8 μM) on the viability (48 h, as determined by the MTT test) of HepG2 cells transfected with small interfering (si) or liver kinase B1 (LKB1)-selective (siLKB1) siRNA. Data correspond to the mean ± standard deviation (S.D.) of four different experiments, each performed in quadruplicate. **P < 0.01 versus control.** Lower panel: LKB1 mRNA levels (mean of the four experiments as determined by real-time quantitative PCR) of HepG2 cells transfected with siC or siLKB1. Right panel: Effect of Δ⁸-THC or JWH-015 (24 h) on the AMPK, ACC, Akt, S6 phosphorylation and microtubule-associated protein 1 light chain 3 (LC3) lipidation of siC- and siLKB1-transfected HepG2 cells. Tubulin levels are shown as loading control. A representative western blot of four different experiments is shown. Optical density (O.D.) values (mean ± S.D. of the four experiments) are shown under the each image. (b) Effect of Δ⁸-THC (8 μM) or JWH-015 (8 μM) on the viability (48 h, as determined by the MTT test) of HepG2 cells transfected with siC- or CaMKKβ-selective (siCaMKKβ) siRNA. Data correspond to the mean ± S.D. of four different experiments, each performed in quadruplicate. **P < 0.01 versus vehicle control;** **P < 0.01 versus cannabinoid-treated cells.** Lower panel: CaMKKβ mRNA levels (mean of the four experiments as determined by real-time quantitative PCR) of HepG2 cells transfected with siC or siCaMKKβ. Right panel: Effect of Δ⁸-THC or JWH-015 (24 h) on AMPK, ACC, Akt and S6 phosphorylation and LC3 lipidation of siC- and siCaMKKβ-transfected HepG2 cells. Tubulin levels are shown as loading control. A representative western blot of four different experiments is shown. O.D. values (mean ± S.D. of the four experiments) are shown under the each image. (c) Effect of Δ⁸-THC (8 μM) or JWH-015 (8 μM) on the viability (48 h, as determined by the MTT test) of HepG2 cells incubated in the presence or absence of the 10 μM STO609 (STO: a CaMKKβ/II inhibitor). Data correspond to the mean ± S.D. of four different experiments, each performed in quadruplicate. **P < 0.01 versus control;** **P < 0.01 versus cannabinoid-treated cells.** Right panel: Effect of Δ⁸-THC, JWH-015 and STO (10 μM) on AMPK, ACC, Akt and S6 phosphorylation and LC3 lipidation (24 h). Tubulin levels are shown as loading control. A representative western blot of four different experiments is shown. O.D. values (mean ± S.D. of the four experiments) are shown under the each image.
cannabinoid treatment almost completely prevented hepato-megaly and ascites. Moreover, levels of the HCC tumor marker α-fetoprotein (AFP) were dramatically reduced in the livers of animals treated with Δ⁹-THC or JWH-015 (Figure 8b). Analysis of tumor samples revealed that cannabinoid treatment enhanced AMPK phosphorylation and inhibited Akt and S6 phosphorylation. Furthermore, THC and JWH-015 enhanced autophagy and apoptosis in these tumors (Figure 8a).

Taken together, these observations robustly support the fact that cannabinoid anti-tumoral action in HCC relies on AMPK stimulation, Akt inhibition and activation of autophagy in HCC cells both in vitro and in vivo.

Discussion
In this study, we show that the natural cannabinoid Δ⁹-THC and the CB₂ receptor-selective agonist JWH-015 inhibit HCC anti-tumoral action of cannabinoids on HCC D Vara et al

Cell Death and Differentiation
cell growth via stimulation of autophagy. Importantly, although the human HCC cell lines used (HepG2 and HuH-7) expressed both CB1 and CB2 receptors, only CB2 activation was involved in the pro-autophagic and anti-proliferative effect induced by cannabinoids on these cells. This is in line with the recent observation that the synthetic cannabinoid WIN-55,212-2-induced apoptosis in HepG2 cells in a process that was partially inhibited by the CB2 receptor-selective antagonist AM630.11 Moreover, it has been previously shown that CB2 receptors are overexpressed in HCC and correlate with good prognosis.31 Those findings, together with ours, support the fact that stimulation of CB2 receptors could be a new therapeutic strategy to promote HCC death.

Our study shows that the mechanism of cannabinoid anti-tumoral action in HCC relies on the stimulation of autophagy and the subsequent activation of apoptosis. Depending on the physiopathological setting, autophagy has been proposed to protect from apoptosis, act as an apoptosis-alternative pathway to induce cell death or act together with apoptosis as a combined mechanism for cell death.32 However, very little is known about the role that the interchange between these two cellular processes have in the control of tumor growth in response to anticancer agents. Our observations are in line with previous results obtained in human glioma cells13 and support the fact that stimulation of autophagy in response to cannabinoid treatment leads to apoptosis. Nevertheless, further research is still necessary to clarify the precise mechanisms linking both cellular processes upon cannabinoid treatment.

Stimulation of autophagy in many cellular settings relies on the inhibition of the mTORC1 complex, which have a central role in the control of protein synthesis, cell growth and cell proliferation through the regulation of several downstream targets. As a result of its central position in the control of cellular homeostasis, mTORC1 integrates signals from different inputs. One of the most important upstream regulators of mTORC1 is the pro-survival kinase Akt, which phosphorylates and inactivates TSC2 (an inhibitor of the mTORC1 activator Rheb) and PRAS-40. Thus, Akt activation stimulates mTORC1 and inhibits autophagy. In this work, we found that cannabinoid treatment of HCC cells leads to Akt and mTORC1 inhibition, which is in agreement with our recent studies in glioma cells.13 Thus, it had been previously shown that inhibition of Akt/mTORC1 pathway by cannabinoids relies on the stimulation of an ER stress-related pathway, which leads to the upregulation of the pseudokinase TRB3, the inhibition of the Akt/mTORC1 axis and the induction of autophagy.13,23 In this study, Δ9-THC and JWH-015 promoted ER stress and increased TRB3 expression. In addition, Akt/mTORC1 inhibition and autophagy were abolished when ceramide biosynthesis was inhibited or when TRB3 expres-

Figure 5 Schematic of the proposed mechanism of cannabinoid-induced hepatocellular carcinoma (HCC) cell death. Cannabinoid treatment stimulates autophagy via two different mechanism: (i) upregulation of tribbles homolog 3 (TRB3) and subsequent inhibition of the serine–threonine kinase Akt/mammalian target of rapamycin C (Akt/mTORC1) axis, and (ii) activation of adenosine monophosphate-activated kinase (AMPK) via CaMKKβ. Stimulation of autophagy by cannabinoids leads to HCC apoptosis and cell death.
Although future research is needed to completely clarify this point, our data suggest that this could be the mechanism by which cannabinoids trigger autophagy in HCC cells.

To note, it has been recently described that mTOR signaling has a critical role in the pathogenesis of HCC and that mTOR inhibitors have antineoplastic activity in experimental models of HCC. Moreover, decreased autophagy in HCC correlates with a more aggressive cancer cell phenotype and poor prognosis. Here we found that cannabinoid treatment reduces the growth of two different models of HCC subcutaneous xenografts in concert with decreased mTORC1 activation, enhanced AMPK phosphorylation and increased autophagy and apoptosis in those tumors. Moreover, knock down of the autophagic gene Atg5 as well as pharmacological inhibition of autophagy dramatically abolished the anti-tumoral activity of cannabinoids against subcutaneous HCC xenografts. Furthermore, Δ9-THC and JWH-015 efficiently reduced ascites development and AFP expression in an orthotypic model of HCC, which also paralleled mTORC1 inhibition, AMPK activation and autophagy stimulation in those tumors. Our data represent the first evidence for the antiproliferative action of cannabinoids in HCC cells in vivo and support that the ability of cannabinoids to inhibit mTORC1, stimulate AMPK and enhance autophagy could be therapeutically exploited for the management of HCC.

Materials and Methods

Reagents. Δ9-THC was obtained from GW Pharm GmbH (Frankfurt, Germany) and JWH-015 was purchased to Sigma (St. Louis, MO, USA). The CB1 antagonist SR-141716 and the CB2 antagonist SR-144528 were kindly provided from Sanofi-Synthelabo (Paris, France). The anti-LC3 polyclonal antibody was obtained from MBL International (Woburn, MA, USA) and the anti-pS6, pAKT-ser473, pACC, ACC, pEIF2α, pAMPK and AMPK polyclonal antibodies were obtained from Cell Signaling Technology (Danvers, MA, USA). The anti-caspase-3 antibody and 3-MA were purchased to Sigma. The inhibitors E64d and PA were purchased to Roche Diagnostics (Mannheim, Germany). The CalpKα/β inhibitor ST0809 was
Figure 7  Autophagy is required for the anti-tumoral action of Δ⁹-tetrahydrocannabinol (Δ⁹-THC) and JWH-015 on hepatocellular carcinoma (HCC) tumor xenografts. (a) Athymic nude mice were injected subcutaneously (s.c.) in the right flank with HepG2 cells. When tumors reached a 150 mm³ size, mice daily treated during 15 days with vehicle (control), 15 mg/kg Δ⁹-THC or 1.5 mg/kg JWH-015. Tumors were injected with atelocollagen complexed with control RNA or atelocollagen complexed with small interfering (si)Atg5 in days 1 and 7 of the treatment. Tumor volumes were measured daily. Tumor growth curves and final tumor volumes after administration of the treatments are shown. Results represent the mean ± standard error of mean (S.E.M.) of eight mice in each group. **P < 0.01 versus control and ##P < 0.01 versus siControl compared by Student’s t-test. Expression levels of Atg5 in siC and siATG5 tumors at the end of the treatment was examined by real-time polymerase chain reaction (PCR). A representative image of the dissected tumors after the treatments is shown. (b) Athymic nude mice injected s.c. in the right flank with HepG2 cells were daily treated during 15 days with vehicle (control) (filled circles), 15 mg/kg Δ⁹-THC (filled squares), 1.5 mg/kg JWH-015 (filled triangles), vehicle plus 1 mg/kg 3-MA (open circles), 15 mg/kg Δ⁹-THC plus 1 mg/kg 3-MA (open squares) or 1.5 mg/kg/JWH-015 plus 1 mg/kg 3-MA (open triangles). Tumor growth curves and final tumor volumes after administration of the treatments are shown. Results represent the mean ± S.E.M. of eight mice in each group. **P < 0.01 versus control and ##P < 0.01 versus cannabinoid-treated tumors compared by Student's t-test. 5'-TATATTCCTGGAGGCTCTACACCC-3'; antisense primer, 5'-GAGCATA CTGCA GAATGCAAACACC-3' (for amplification of a 270-bp product for human CB1); and CB2 sense primer, 5'-TTTCCCCACTGATCCCCAATG-3'; antisense primer, 5'-GAGCATACTGCAATGCAAACACC-3' (for amplification of a 333-bp product for human CB2). PCR products were analyzed by electrophoresis on ethidium bromide-stained 2% agarose gels and DNA was detected by exposure under UV light.

**Western blot.** After different treatments according to the experiments cells were lysed in ice-cold lysis buffer (50 mM Tris (pH 7.4), 0.8 M NaCl, 5 mM MgCl₂, 0.1% Triton X-100, 1 mM PMSF, 10 µg/ml soybean trypsin inhibitor, 1 µg/ml aprotinin and 5 µg/ml leupeptin), and cleared by microcentrifugation. Equivalent protein amounts of each sample were separated on SDS-PAGE gels and blotted to PVDF transfer membrane. After blocking with 5% skim dried milk, immunoblot analysis was performed followed by enhanced chemo luminescence detection.

**Cell viability assay.** Cells in logarithmic phase were cultured at a density of 5000 cells per cm² in a 12-well plate. The cells were exposed to various concentrations of Δ⁹-THC and JWH-015 for indicated times. The 3-[4,5-dimethylthiazolyl-2] 2,5-diphenyl-tetrazolium bromide (MTT) cell viability assay was used to evaluate the effects of cannabinoids on cell growth and to determine the IC₅₀.

**Confocal microscopy.** After 48 h in culture, the cells were fixed in 4% paraformaldehyde in PBS and incubated with 0.1% Triton X-100 for permeabilization. Immunolabeling with the anti-LC3 polyclonal antibody was performed by incubation.
at room temperature for 1 h. Secondary labeling was performed with Alexa Flour 594, conjugated to anti-rabbit IgG and Alexa Flour 488 (Invitrogen). Imaging was with a Leica TCS SP5 laser-scanning confocal microscope with LAS-AF imaging software, using a 63 × 0.16 oil objective.

**siRNA transfections.** Cells were seeded at 2 × 10^5 cells/35 mm well the day before transfection. Cells were then transfected in 1 ml OPTIMEN containing 4 μg Lipofectamine 2000 (Invitrogen), with 100 nM siRNA duplexes or control scrambled RNA according to the manufacturer’s protocols. 24 h after transfection, the medium was removed and replaced for DMEM containing 10% fetal bovine serum. Cells were then treated with cannabinoids for 48 h and used for MTT cell viability assays.

For each transfection, the following sequences were used: Atg 5 sense sequence, 5′-GUGGAGAUUGGGUUGAUAUdTdT-3′; Atg 5 antisense primer, 5′-CAGAAGGUUUGGCGAGUAdTdT-3′; sense sequence, 5′-GAATCTCCTGACGCAAtTdTdT-3′; sense sequence, 5′-GCCAGAGGUGAAUAGUUGUAdTdT-3′; CaMKKβ sense primer, 5′-GACCAUGUGGUGGAGUAdTdT-3′; LKB1 sense sequence, 5′-GUACUUCUGCUGACUAUUtTd-3′; CaMKKβ sense sequence, 5′-GCUCUACUGUGGUUGUGUAdTdT-3′ (Sigma).

**Real-time quantitative PCR.** cDNA was obtained from cells using Transcripter (Roche Applied Science, Mannheim, Germany). Real-time quantitative (qPCR) assays were performed using the FastStart Universal Probe Master mix with Rox (Roche Applied Science), and probes were obtained from the Universal ProbeLibrary Set (Roche Applied Science). Atg 5 sense primer, 5′-GACGCTGTTAATGCAUGGUGT-3′; Atg 5 antisense primer, 5′-TAGAGGATCTCCAAGGGTATGCA-3′; sense sequence, 5′-GCTGCCTTGCCCGAGTATGA-3′; CaMKKβ sense primer, 5′-GGCTGAGGAATGATGGCAGG-3′; LKB1 sense primer, 5′-GGGATCTGCTGCGCCGAGAGTGATGA-3′; LKB1 antisense primer, 5′-GGTATCTGCTGCGCCGAGAGTGATGA-3′; sense sequence, 5′-GCCCAGAGGUGUAGAUAUAUGUAdTdT-3′; 18S sense primer, 5′-GUACUUCUGCUGACUAUUtTd-3′;

**Statistical analysis.** Cell viability data were expressed as the mean ± S.D. and evaluated by Student’s t-test. Differences were considered significant when the P-value was less than 0.05.
